I would solve this problem by using a Backend for Frontend (BFF). Instead of calling 15 services from the mobile app, the app sends only one request to the BFF. The BFF collects all the data and sends it back to the app.

Some services need data from other services, so we cannot call all of them at the same time. To solve this, we can prepare the data before the user opens the app and store it in one place. We can keep this data updated so it is never more than one hour old. This way, the app does not need to wait for all 15 services, and we have a better chance of getting the data in less than 2.5 seconds.
